(57) **ABSTRACT**

A method of exchanging value across a blockchain network comprising receiving first and second transaction smart contracts, recording the first transaction smart contract to the second transaction smart contract, and registering global variable names and defining values thereof. The method further comprises receiving a transaction notification and recording the transaction to the second transaction smart contract.

TOKENS OR CRYPTO CURRENCY USING SMART CONTRACTS AND BLOCKCHAINS

RELATED APPLICATIONS

This application claims the benefit under 35 U.S.C. § 119(e) of U.S. Provisional Patent Application Ser. No. 62/557,820 filed on Sep. 13, 2017 and titled Tokens or Crypto Currency for Change Using Smart Contracts and Blockchains, and U.S. Provisional Patent Application Ser. No. 62/618,784 filed on Jan. 18, 2018 and titled Additional Features of CoinBank and nCash NCC Tokens, the entire contents of which is herein by reference.

FIELD OF THE INVENTION

The present invention relates to systems and methods for improving the linking smart contracts in transactions on a blockchain network.

BACKGROUND

Blockchain is a distributed and public ledger which maintains records of all the transactions. A blockchain network is a truly peer-to-peer network and it does not require a trusted central authority or intermediaries to authenticate or to settle the transactions or to control the network infrastructure. Users can interact and transact with the blockchain networks through Externally Owned Account (EOAs), which are owned and controlled by the users. Each EOA has a balance (in certain units of a Cryptocurrency associated with the Blockchain network) associated with it. EOAs do not have any associated code. All transactions on a blockchain network are initiated by EOAs. These accounts can send transactions to other EOAs or contract accounts. Another type of accounts support by second generation programmable Blockchain platforms are the Contract Accounts. A Contract Account is created and owned by an EOA and is controlled by the associated contract code which is stored with the account. The contract code execution is triggered by transactions sent by EOAs or messages sent by other contracts.

Blockchain networks can either be public or private. Public blockchain networks are free and open to all and any user can create an account and participate in the consensus mechanism on a public blockchain and view all the transactions on the network. Private blockchain networks are usually controlled and operated by a single organization and the transactions can be viewed only by the users within the organization. Public blockchain networks are usually unpermissioned or permissionless, as any node can participate in consensus process. Some public blockchain networks adopt a permissioned model where the consensus process is controlled by a pre-selected set of nodes. Private blockchain networks usually adopt the permissioned model. While public blockchain networks can be considered as fully decentralized, private blockchain networks are partially decentralized.

Organizations can have multiple private blockchain networks where each network is dedicated to a specific use case or department or business vertical. The blockchain networks within an organization may be created either using the same blockchain platform or technology or with different platforms or technologies.

On each blockchain network, a user can create multiple Externally Owned Accounts (EOAs). Each Externally Owned Account (EOA) has a public-private keypair asso-

2

ciated with it. The account address is derived from the public key. When a new EOA is created, a keyfile is created which has the public and private keys associated with the account. The private key is encrypted with the password which is provided while creating the account. For sending transactions to other accounts, the private key and the account password are required.

This background information is provided to reveal information believed by the applicant to be of possible relevance to the present invention. No admission is necessarily intended, nor should be construed, that any of the preceding information constitutes prior art against the present invention.

SUMMARY OF THE INVENTION

With the above in mind, embodiments of the present invention are directed to a system and associated methods for exchange of information, value or tokens within and between blockchain networks and the real physical world.

In some embodiments, the systems, apparatus and methods allow creation and deployment of scalable blockchain applications that rely on a large number of smart contracts that interact with each other through the use of either a cloud-based billboard architecture or a blockchain-based billboard architecture. This architecture allows extension of existing blockchain applications to deploy smart contracts that use global shared variables (within languages, such as Solidity) to exchange information with each other. The billboard architecture allows the integration of scalable information exchange between the real-world (e.g., triggers such as loan payments or sales of products) and the systems of smart contracts and oracles, seamlessly and efficiently. Several familiar programming models such as push/pull, publish/subscribe and consumer/producer may be easily supported for production deployment.

Decentralized blockchain applications and smart contracts in second and third generation blockchain platforms such as Ethereum, Hyperledger, Neo, Lisk and EOS that rely on a large number of linked smart contracts interacting with each other can benefit from the proposed Bulletin Board Messaging Framework (BBMF) and the Global Variable Name System (GVNS) technologies. In current implementations of applications with linked smart contracts, one smart contract can send a transaction to another contract or reference public state variables of other contracts. However, such calls and variable references must be coded in the smart contract and the contract code once deployed cannot be changed. If one contract in a system of linked contracts must be changed then it would need re-deployment of all the other linked contracts as the code has to be changed. BBMF and GVNS technologies allow the seamless integration of scalable information exchange between the real-world and the systems of smart contracts and oracles, seamlessly and efficiently. Further, legacy blockchain-based code can be seamlessly upgraded and functionality modified through change in the BBMF framework through new mapping and distribution from older public state variables to new or redefined ones.

In some embodiments, the method and systems may further comprise fintech and enterprise applications, including but not limited retail payments, loyalty rewards and peer-to-peer lending application (referred as nCash mobile application) and an associated platform (referred as nCash Network) that provide the following features:

Scalable blockchain architecture that links to the real-world: Decentralized applications and systems that are

based on a very large number of interacting smart contracts that are coupled with and responsive to real world triggers and events, using a novel billboard-based information and value distribution system.

Secure Blockchain Payments: The platform is built on second generation programmable Blockchain network (such as Ethereum) and allows individuals to securely send and receive payments.

Pay At Merchant Stores: The nCash application allows users to spend crypto or fiat currencies managed by the platform at affiliated merchant stores.

Get Change in Tokens: Users no longer have to deal with the inconvenience of receiving loose change back when making purchases, rather they can receive the change into their mobile application wallet.

Loyalty Rewards & Offers: Users can get exclusive loyalty rewards, discount offers and cashbacks by paying with nCash app at affiliated merchant stores.

Supports Multiple Currencies: The nCash mobile application wallet is capable of managing multiple layers of currencies (fiat currency, cryptocurrency and ERC-20 tokens). Users can buy the native tokens named nCash Coins (NCC) by paying with credit or debit card, ACH bank transfer, or any of the supported cryptocurrencies (including Bitcoin, Ether, Litecoin, and more).

ERC20 Token: nCash coins (NCC) are based on the ERC-20 token standard. NCC tokens can be purchased with any of the supported fiat or crypto currencies in the nCash app.

Chat & Transact with Contacts: With nCash users can chat and send payments, or request payments from their contacts.

Borrow & Lend Coins: nCash application includes a lending marketplace and supports borrowing and lending of nCash coins.

Multiple Account Types: nCash application supports customer, merchant admin and merchant operator account types.

Additionally, embodiments of the present invention are directed to a method of exchanging value across a blockchain network comprising receiving a first transaction smart contract, that may be a transaction, comprising a transaction amount global variable name request and a transaction amount, recording the first transaction to a second transaction smart contract on a first blockchain network, and registering the first transaction amount global variable name to a global variable name system, defining a transaction amount global variable. The method further comprises defining a value of the transaction amount global variable responsive to the transaction amount, receiving a second transaction smart contract, which may also be a financial transaction, comprising a second transaction global variable name request and a second transaction amount, and registering the second transaction global variable name request to the global variable name system, defining a second transaction global variable. The method further comprises defining a value of the second transaction global variable responsive to the second transaction amount, receiving a transaction notification comprising the second transaction global variable name and a transaction value, recording the transaction notification to the second smart contract, and updating the value of the second transaction global variable responsive to the transaction value.

In some embodiments, updating the value of the second transaction global variable may comprise publishing the updated value of the second transaction global variable to a first managed topic on a first messaging server and trans-

mitting the content published to the managed topic to a first subscriber. The receipt of the content published to the first managed topic by the first subscriber may initiate a smart contract transaction for a first smart contract, the first smart contract being recorded on a first blockchain network.

Registering the transaction amount global variable, registering the second transaction global variable, and registering the registering the second transaction global variable each comprise performing a global variable registration process may comprise receiving a request for to register a global variable name at a global variable name registrar from a user, defining a new global variable, defining an owner for the new global variable at a global variable name registry, defining a resolver for the new global variable at the global variable name registry, and defining a value of the new global variable. Additionally, the method may further comprise performing an updating procedure to update the value of the new global variable, the updating procedure comprising receiving a trigger generated by a smart contract data source on a first messaging server, the trigger comprising an updated value of the new global variable, publishing the updated value comprised by the trigger to a first managed topic associated with the new global variable on the first messaging server, and transmitting the updated value comprised by the trigger that is published to the managed topic to a first subscriber. Receipt of the content published to the first managed topic by the first subscriber may initiate a smart contract transaction for a first smart contract, the first smart contract being recorded on the first blockchain network.

In some embodiments, the method may further comprise receiving a collateral input and recording the collateral input to a collateral smart contract on the first blockchain network. The collateral input may be a collateral token generated by receiving a tangible asset collateral deposit, generating a collateral token associated with the tangible asset collateral deposit, and transmitting the collateral token. The tangible asset may be received by a third party and the collateral token may be generated by the third party. In some embodiments, the method may further comprise receiving a repayment notification, recording the repayment notification to the second transaction smart contract, updating the value of the second transaction global variable, and recording a collateral release to the collateral smart contract. In some embodiments, the method may further comprise receiving a default notification, recording the default notification to the second transaction smart contract, updating the value of the second transaction global variable, and recording a collateral release to the collateral smart contract directed to the second transaction global variable. The collateral input may comprise at least one of cryptocurrency or a collateral token.

In some embodiments, the method may further comprise receiving an installation payment, recording an installation payment notification to the second transaction smart contract, updating the second transaction global variable responsive to a value of the installation payment, and transferring at least a portion of the value of the installation payment to an entity associated with the second transaction global variable.

In some embodiments, the first transaction smart contract may further comprise a loan duration and a loan interest rate, collectively defining borrower conditions, the method further comprising registering a loan duration global variable name to the global variable name system, defining a loan duration global variable, defining a value of the loan duration global variable responsive to the transaction amount, registering a loan interest rate global variable name to the

global variable name system, defining a loan interest rate global variable, and defining a value of the loan interest rate global variable responsive to the loan interest rate. The method may further comprise receiving a plurality of lending offers from a plurality of lenders, each lending offer comprising an amount to lend, a loan duration, and expected returns, collectively defining lending pool conditions, recording the plurality of lending offers, defining a lending pool, to a second transaction smart contract on the first blockchain network, the values of the lending offers of the plurality of lending offers defining lending pool conditions, determining if the borrower conditions match the lending pool conditions, matching a lending offer from the second transaction smart contract to the first transaction, recording a borrower smart contract between the borrower and the second transaction smart contract, and recording a lender smart contract between the lender associated with the matched lending offer and the second transaction smart contract. Additionally, the method may further comprise receiving multiple pluralities of lending offers from a plurality of lenders, each lending offer comprising an amount to lend, a loan duration, and expected returns, recording each plurality of lending offers, defining a lending pool, to a second transaction smart contract on the first blockchain network, the values of the lending offers of the plurality of lending offers defining lending pool conditions, recording a plurality of second transaction smart contracts to a pool of pools smart contract on the first blockchain network, determining if the borrower conditions match the lending pool conditions of any of the plurality of second transaction smart contracts comprised by the pool of pools smart contract, matching a lending offer from the pool of pools smart contract to the first transaction, recording a borrower smart contract between the borrower and the pool of pools smart contract, recording a pool-to-pool smart contract between the pool of pools smart contract and the second transaction smart contract, and recording a lender smart contract between the lender associated with the matched lending offer and the second transaction smart contract.

In some embodiments, the method may further comprise receiving borrower identity information associated with a borrower, receiving a borrower credit rating, and recording the borrower credit rating to a credit rating and reputation smart contract on the first blockchain network.

Additional embodiments of the inventions may be directed to a system for exchanging value across a blockchain network comprising a processor, a data store positioned in communication with the processor, and a network communication device positioned in communication with each of the processor, the data store, and a network. The network communication device may be operable to receive a first transaction smart contract comprising a transaction amount global variable name request and a transaction amount. The processor may be operable to record the first transaction to a second transaction smart contract on a first blockchain network and register the first transaction amount global variable name to a global variable name system, defining a transaction amount global variable. Additionally, the network communication device may be operable to receive a second transaction smart contract comprising a second transaction global variable name request and a second transaction amount. Furthermore, the processor may be operable to register the second transaction global variable name request to the global variable name system, defining a second transaction global variable. The network communication device may be operable to receive a transaction notification comprising the second transaction global vari-

able name and a transaction value. The processor may be operable to record the transaction notification to the second transaction smart contract and update a value of the second transaction global variable responsive to the transaction value.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a schematic diagram of a retail payments, loyalty rewards and peer-to-peer lending system that uses smart contracts and blockchain.

FIG. 2 is an illustration of a process for retail payments where a customer pays in cash at a merchant kiosk/application/point of sale application or hardware device that is aware of the nCash platform, and instead of receiving loose change back receives digital tokens in the nCash mobile application wallet, according to an embodiment of the invention.

FIG. 3 is an illustration of a process for retail payments where a customer pays in cash and instead of receiving loose change back receives digital tokens from a merchant account in the nCash mobile application, according to an embodiment of the invention.

FIG. 4 is an illustration of the components of the nCash mobile application wallet, according to an embodiment of the invention.

FIG. 5 is an illustration a process for QR-code based payment request and authorization, according to an embodiment of the invention.

FIG. 6 is an illustration of a process for buying coins with credit or debit card, according to an embodiment of the invention.

FIG. 7 is an illustration of a process for buying coins with ACH Bank Transfer, according to an embodiment of the invention.

FIG. 8 is an illustration of a process for buying coins with Cryptocurrencies, according to an embodiment of the invention.

FIG. 9 is an illustration a process for withdrawing coins to a linked bank account, according to an embodiment of the invention.

FIG. 10 is an illustration of the smart contracts involved in the nCash retail payments, loyalty rewards and peer-to-peer lending platform, according to an embodiment of the invention.

FIG. 11 is an illustration of a process for peer-to-peer lending, according to an embodiment of the invention.

FIG. 12 is a schematic diagram of the blockchain-based peer-to-peer lending system, according to an embodiment of the invention.

FIG. 13 is an illustration the multi-signature collateral contract used by the peer-to-peer lending system, according to an embodiment of the invention.

FIG. 14 is an illustration of a process for chaining of loans, according to an embodiment of the invention.

FIG. 15 is an illustration of a process for lending with cryptocurrency or tokens as collateral where the borrower successfully repays the loan, according to an embodiment of the invention.

FIG. 16 is an illustration of a process for lending with cryptocurrency or tokens as collateral where the borrower fails to repay the loan, according to an embodiment of the invention.

FIG. 17 is an illustration of a process for lending with physical assets as collateral, according to an embodiment of the invention.

FIG. 18 is an illustration of the transaction fee involved for buying and selling of coins, according to an embodiment of the invention.

FIG. 19 is an illustration of the smart contracts related to the lending platform and the interactions of borrowers and lenders with the smart contracts, according to an embodiment of the invention.

FIG. 20 is an illustration of a process for issuing cashback and discounts using smart contracts, according to an embodiment of the invention.

FIG. 21 is an illustration of a peer-to-pool-to-peer (P2P2P) lending model, according to an embodiment of the invention.

FIG. 22 is an illustration of a lending pool generator for generating lending pool smart contracts, according to an embodiment of the invention.

FIG. 23 is an illustration of a matching engine for matching borrowers to lending pools, according to an embodiment of the invention.

FIG. 24 is an illustration of feeding external data to lending pool contracts using an oracle, according to an embodiment of the invention.

FIG. 25 is an illustration of channels and triggers for lending pools, according to an embodiment of the invention.

FIG. 26 is an illustration of smart contracts involved in a lending pool, according to an embodiment of the invention.

FIG. 27 is an illustration of a pool-of-pools comprised of multiple lending pools, according to an embodiment of the invention.

FIG. 28 is an illustration of a lending pool smart contract structure and transactions, according to an embodiment of the invention.

FIG. 29 is an exemplary classification of lending pools based on their risk and returns, according to an embodiment of the invention.

FIG. 30 is an illustration of an alliance of merchants with interoperable loyalty points, according to an embodiment of the invention.

FIG. 31 is an illustration of a distributed messaging framework called Bulleting Board Messaging Framework (BBMF) according to an embodiment of the invention.

FIG. 32 is an illustration of consumer/subscriber actions supported in the publish-subscribe messaging framework illustrated in FIG. 31.

FIG. 33 is an illustration of a smart contract data source that uses an external publisher client to publish messages to the publish-subscribe messaging framework, according to an embodiment of the invention.

FIG. 34 is an illustration of a smart contract data source that uses an integrated publisher client to publish messages to the publish-subscribe messaging framework, according to an embodiment of the invention.

FIG. 35 is an illustration of the message format for the publish-subscribe messaging framework, according to an embodiment of the invention.

FIG. 36 is an illustration of a global variable name system being updated by a consumer of the publish-subscribe messaging framework, according to an embodiment of the invention.

FIG. 37 is an illustration of the architecture of a global variable name system, according to an embodiment of the invention.

FIG. 38 is an illustration of a blockchain checkpointing approach in the publish-subscribe messaging framework, according to an embodiment of the invention.

FIG. 39 is an illustration of global variable sharing across smart contracts, according to an embodiment of the invention.

FIG. 40 is an exemplary implementation of a Bulletin Board Publisher/Producer client and Consumer/Subscriber client, according to an embodiment of the invention.

FIG. 41 is an exemplary interface of the nCash mobile application, according to an embodiment of the invention.

FIG. 42 is an exemplary interface of the nCash mobile application showing peer-to-peer lending options, according to an embodiment of the invention.

FIG. 43 is an exemplary interface of the nCash mobile application showing different types of transactions, according to an embodiment of the invention.

FIG. 44 is an exemplary interface of the nCash mobile application showing chats and payments interface, according to an embodiment of the invention.

FIG. 45 is an illustration of the nCash mobile application features for different types of accounts, according to an embodiment of the invention.

DETAILED DESCRIPTION OF THE INVENTION

The present invention will now be described more fully hereinafter with reference to the accompanying drawings, in which preferred embodiments of the invention are shown. This invention may, however, be embodied in many different forms and should not be construed as limited to the embodiments set forth herein. Rather, these embodiments are provided so that this disclosure will be thorough and complete, and will fully convey the scope of the invention to those skilled in the art. Those of ordinary skill in the art realize that the following descriptions of the embodiments of the present invention are illustrative and are not intended to be limiting in any way. Other embodiments of the present invention will readily suggest themselves to such skilled persons having the benefit of this disclosure. Like numbers refer to like elements throughout.

Although the following detailed description contains many specifics for the purposes of illustration, anyone of ordinary skill in the art will appreciate that many variations and alterations to the following details are within the scope of the invention. Accordingly, the following embodiments of the invention are set forth without any loss of generality to, and without imposing limitations upon, the claimed invention.

In this detailed description of the present invention, a person skilled in the art should note that directional terms, such as “above,” “below,” “upper,” “lower,” and other like terms are used for the convenience of the reader in reference to the drawings. Also, a person skilled in the art should notice this description may contain other terminology to convey position, orientation, and direction without departing from the principles of the present invention.

Furthermore, in this detailed description, a person skilled in the art should note that quantitative qualifying terms such as “generally,” “substantially,” “mostly,” and other terms are used, in general, to mean that the referred to object, characteristic, or quality constitutes a majority of the subject of the reference. The meaning of any of these terms is dependent upon the context within which it is used, and the meaning may be expressly modified.

Referring now to FIG. 1 a schematic diagram of a retail payments, loyalty rewards and peer-to-peer lending system that uses smart contracts and blockchain, is described in more detail. A user 100 and a merchant 102 may complete

a transaction through use of an application and presentation layer **104**. The application and presentation layer **104** may comprise a web interface **106** and/or a mobile application **108**. Elements of the application and presentation layer **104** may be the client-facing element of a platform/application services layer **110**. The platform/application services layer **110** may comprise security features **112**, such as a user identity and access management system **114**. The platform/application services layer **110** may further comprise integration services **116**, such as, for example, a messaging service **118** or a connector service for applications, cloud services, and token exchanges **120**. The platform/application services layer **110** may further comprise configuration management features **122**. The configuration management features **122** may include an nCash portal **124**, an incentives management system **126**, and a license manager **128**. The platform/application services layer **110** may further comprise accounting and transaction services **130**, such as a change management framework **132**, a token framework **469**, an incentives disbursement framework **136**, a lending framework **138**, and an nCash wallet **140**. The platform/application services layer **110** may further comprise data management and analytics services **142**, such as analytics and reporting systems **144**, an incentives bidding system **146**, a loan matching system **148**, a recommendation system **150**, and an advertisement and promotions system **152**. The platform/application services layer **110** may function on an infrastructure layer **154** that may comprise one or more of blockchain networks **156**, decentralized storage platforms **158**, decentralized messaging platforms **160**, or cloud infrastructure **162**, such as cloud computational resources, cloud storage resources, or cloud networking resources.

Referring now to FIG. 2 a process flow for retail payments where a customer pays in cash and instead of receiving loose change back, receives the change as digital tokens (nCash coins—"NCC") in the nCash mobile application, is described in more detail. Customer **200** pays for the items purchased or rented at a store in cash at step **204**. Customer **200** opens the nCash app and displays a barcode of the customer's nCash account number at step **206**. The merchant kiosk/application/point of sale application or hardware device that is aware of the nCash platform **202** scans the barcode and an entry is added in the ledger to transfer the change to the nCash account at step **208**. At some periodic interval, for example, at the end of the day, all the transactions to credit the change to nCash accounts are processed by the payment system. Customer **200** receives the change back in the nCash App at step **210**.

Referring now to FIG. 3 a process flow for retail payments where a customer pays in cash and instead of receiving loose change back receives digital tokens from a merchant account in the nCash mobile application, is described in more detail. Customer **220** pays for the items purchased or rented at a store in cash at step **224**. Customer **220** opens the nCash app and displays a QR code at step **226**. The merchant/PoS agent **222** that has a mobile/tablet device with nCash mobile application installed scans the QR code and enters the change amount and transfers the amount instantly from the merchant administrator or operator account at step **228**. Every PoS agent **222** has a Merchant nCash app to which some fixed amount is loaded by the store daily to pay as change. Customer **220** receives the change back in the nCash App at step **230**.

Referring now to FIG. 4 components of an nCash mobile application wallet **250** are described in more detail. The nCash wallet **250** may comprise a Fiat currency wallet **252**, a cryptocurrency wallet **258**, a coupons and voucher man-

agement system **254**, and ERC-20 token wallet **260**, Escrow accounts **256**, and prepaid credit accounts **262**. For making retail payments, a portion or prepaid deposit in fiat or cryptocurrency wallets **252**, **258** can be considered. The wallet balance of one or both of the fiat and cryptocurrency wallets **252**, **258** may be applied to Escrow **256** as well where the payment sent by a customer to a merchant is held in an Escrow account and released when an order is fulfilled.

Referring now to FIG. 5 a process flow for QR-code based payment request and authorization, is described in more detail. Customer **302** uses nCash mobile application to display a QR code containing customer's nCash wallet address and a one-time receive code at step **318**. The QR code is scanned by a PoS machine **306** or nCash app with merchant account **308**, and a request is sent including the customer address, the receive code, and the amount to the nCash network **300** at step **316**. The nCash network **300** validates the receive code and sends a request to customer to authorize the payment at step **312**. Customer **302** authorizes the payment from the nCash app at step **314**. A payment confirmation is sent to the PoS machine **306** or nCash app with merchant account **308**, at step **310**.

Referring now to FIG. 6 a process flow for buying coins with credit or debit card is described in more detail. Customer **350** sends a request to load an amount to nCash wallet using credit or debit card at step **356**. The nCash network **352** requests for credit or debit card details of customer **350** at step **358**. Customer **350** enters credit or debit card information in the nCash mobile application at step **360**. The card information is then sent to the fiat payment processor **354** directly without going through the nCash network **352** at step **360**. The fiat payment processor **354** validates the card information and generates a token which is then sent to customer's nCash mobile application at step **362**. Customer **350** confirms the payment and sends a request containing the card token and payment amount at step **364**. The nCash network **352** sends a request containing the token and the payment amount to charge the card to the fiat payment processor **354** at step **366**. The fiat payment processor **354** charges the customer's card for the amount requested and a payment confirmation is sent to the nCash network **352** at step **368**. The nCash network **352** mints new coins (digital tokens defined in the nCash Token smart contract) and the token smart contract **370**. The nCash network **352** adds these new coins (digital tokens) the customer's nCash wallet account at step **372**.

Referring now to FIG. 7 a process flow for buying coins with ACH Bank Transfer is described in more detail. Customer **400** sends a request to an nCash network **402** to load an amount to nCash wallet using ACH bank transfer at step **406**. The nCash network **402** requests a temporary account details from a fiat payment processor **404** at step **408**. The fiat payment processor **404** generates a temporary account and sends details about the temporary account to the nCash network **402** at step **410**. The nCash network **402** then sends the temporary account details to the customer's nCash mobile application. Customer **400** sends a payment to the temporary account using ACH bank transfer at step **414**. On receiving the payment, the fiat payment processor **404** sends a payment confirmation to nCash network **402** at step **416**. The nCash network **402** mints new coins (digital tokens defined in the nCash Token smart contract) and the token smart contract **418**. The nCash network **402** adds these new coins (digital tokens) the customer's nCash wallet account at step **420**.

Referring now to FIG. 8 a process flow for buying coins with Cryptocurrencies is described in more detail. Customer

11

450 sends a request to an nCash network 452 to load an amount to nCash wallet using cryptocurrency at step 456. The nCash network 452 requests a temporary account details from a crypto payment processor 454 at step 458. The crypto payment processor 454 generates temporary account and sends them to the nCash network 452 at step 460. The nCash network 452 then sends the temporary account details to the customer's nCash mobile application at step 462. Customer 450 sends a payment to the temporary account using a cryptocurrency wallet at step 470. On receiving the payment, the crypto payment processor 454 sends a payment confirmation to nCash network 452 at step 472. The nCash network 452 mints new coins (digital tokens defined in the nCash Token smart contract) and the token smart contract 480. The nCash network 452 adds these new coins (digital tokens) the customer's nCash wallet account at step 482.

Referring now to FIG. 9 a process flow for withdrawing coins to a linked bank account is described in more detail. Customer 500 sends a request to a nCash network 502 to withdraw a certain amount of tokens to customer's linked bank account in a bank 506 at step 508. On receiving the withdrawal request the nCash network 502 burns coins equivalent to the withdrawal amount from the customer's account and updates the token smart contract 510. The nCash network 502 then sends a transfer request to the fiat payment processor 504 at step 512. The withdrawal amount is credited by the fiat payment processor 504 to the customer's linked bank account at the bank 506 at step 514. The fiat payment processor 504 then sends a transfer confirmation to nCash network 502 at step 518. A withdrawal confirmation is then sent to customer 500 at step 520.

Referring now to FIG. 10 examples of smart contracts involved in the nCash retail payments, loyalty rewards, and peer-to-peer lending platform are described in more detail. The nCash blockchain network 588 is a distributed ledger which maintains records of all the transactions on the nCash network. Users 554 interact and transact with the blockchain network 588 through Externally Owned Account (EOAs) 550, which are owned and controlled by the users. Each EOA 550 has an account address 556, account public-private keys 558 and a balance 560 (in certain units of a Cryptocurrency associated with the Blockchain network) associated with it. EOAs do not have any associated code. EOAs may interact 564 with bank accounts 552 also owned 566 by the user 554 via third party exchanges operable to exchange cryptocurrencies for fiat currency, which may be deposited in or withdrawn from the bank account 552.

All transactions on a blockchain network are initiated by EOAs. These accounts can send transactions to other EOAs or contract accounts. Another type of accounts support by second generation programmable Blockchain platforms are the Contract Accounts. Smart contracts 570 contain the contract code which control the associated contract accounts. The smart contracts 570 are deployed on the blockchain network 588. The smart contracts 570 involved in the nCash network are as follows:

Token Contract 572: Token Contract provides the nCash token definition including token name, symbol, decimal places, token supply, method for token transfer, and method for checking token balance of an account. Token Distribution Contract 580: Token Distribution Contract defines the token distribution and pricing model and contains methods for purchasing and claiming tokens, and methods for withdrawing token sale proceeds.

12

Incentives Contract 574: Incentives Contract defines the incentives and triggers and methods for distributing incentives.

Bidding Contract 582: Bidding Contract defines the bidding mechanism for allowing merchants to compete, bid, or pay for the right to add incentives.

Loan Smart Contract 576: Loan Smart Contract is used to enforce loan terms, manage release, repayment or extension of loans.

Identity Smart Contract 584: Identity Smart Contract is used to link blockchain accounts to real users (borrowers or lenders).

Credit Rating & Reputation Smart Contract 578: Credit Rating & Reputation Smart Contract is Used to track credit scores and reputation of borrowers.

Collateral Smart Contract 586: Collateral Smart Contract is used to manage locking up and release of collateral, such as cryptocurrency tokens or physical assets which may be represented in a tokenized form.

Referring now to FIG. 11 a process flow for peer-to-peer lending is described in more detail. A borrowing peer (borrower) 600 creates a first transaction smart contract in the form of a loan request at step 606. The lending platform 602 advertises the loan requests to the lending peers (lenders) 604 at step 616. The lending platform 602 may acquire a credit rating 612 associated with the borrowing peer 600 and include the credit rating with the request. The lending peers 604 bid for loans by sending second transaction smart contracts in the form of loan offers to the lending platform 602 at step 620. The borrowing peer 600 selects the best offer and the loan amount is sent to the borrowing peer at step 610. The borrowing peer 600 repays the loan amount plus the interest and lending platform fees to the lending platform 602 at step 608. The lending platform 602 returns the loan amount plus the profit to the lending peer 604 at step 618. The lending platform 602 may issue loyalty points 614 to borrowing peers 600 and lending peers 604 upon successful repayment of loans, to incentivize the borrowing and lending peers 600, 604 to use the lending platform again for borrowing and lending.

Referring now to FIG. 12 a schematic diagram of the blockchain-based peer-to-peer lending system is described in more detail. The blockchain-based peer-to-peer lending system allows borrowing peers or borrowers 652 to send loan requests to a platform 650 which are advertised to lending peers or lenders 656. Lenders 656 can bid to send a loan at a particular rate and terms that is enforced by a loan smart contract 668 deployed on a blockchain network 678. The lending platform 650 can co-exist with an electronic payments platform. A Borrowers 652 post loan requests to the platform and rates they can pay and lenders bid for loans with terms and rates. Platform 650 allows borrowers 652 to automatically repay loans from their nCash mobile application wallets (Borrower Crypto wallet) 662 or extend loan for another term if agreed to. Platform 650 can disburse loans in fiat or crypto currencies. When a loan is disbursed, the loan amount is transferred from the Lender Crypto wallet 672 (nCash mobile application wallet of the lender) to the Borrower Crypto wallet 662 (nCash mobile application wallet of the borrower). The interest rate is driven by the market. Higher risk means larger rate. Platform 650 may charge a percentage of the interest rate on every transaction. Borrower Identity Smart Contracts 658 comprised by the platform 650 maintain the identity information of the borrowers 652. Lender Identity Smart Contracts 670 comprised by the platform 650 maintain the identity information of the lenders 656. Borrower Reputation and Credit Rating Smart

13

Contracts **660** comprised by the platform **650** maintain the reputation information of the borrowers **652** and their credit ratings. Collateral Smart Contracts **664** comprised by the platform **650** maintain collateral information for the loans. A reputation system and collaterals for loans makes the lending process more reliable. The lending platform **650** uses smart contracts to create a credit rating and reputation system for borrowers. Each repayment and successful loan adds points to the borrower's credit rating and if a loan is not repaid then points are deducted from the borrower's credit rating. Such payments may be transferred to a cryptocurrency wallet **672** for the lender **656**. If a borrower **652** requesting a loan does not repay as per conditions their credit rating/reputation drops and lenders **656** will charge extremely high rates and higher guarantees for any subsequent loan requests. The amount of loans could be against a collateral account by the borrower **652** or having pledges from guarantor **654** or other peers that they will guarantee a certain portion of loan. The risk score gets lower of a borrower has pledges to support him. If risk score suddenly changes existing lenders get an alert that they can opt for a higher rate or a shorter repayment term. This forces the borrower to borrow wisely to protect against these margin calls. Loans issued through the platform **650** may be secured (backed by collateral) or unsecured. A Matching Engine **666** of the platform **650** matches loan requests to loan offers and connects the borrowers to lenders. The platform matches borrowers to lenders by risk reputation, loan value and interest terms. For secured loans, borrowers **652** or their guarantors **654** may present collateral in the form of Cryptocurrency Tokens or Tokenized Assets. When Cryptocurrency Tokens are presented as collateral such tokens are transferred by the borrower to a collateral contract where the tokens are held until the loan is not repaid. When the loan is repaid, the tokens are released to the borrower **652**. If the loan is not repaid, the tokens are released to the lender **656**. Physical assets (such as gold, diamonds, real-estate property) may be tokenized and presented as a collateral. For such cases, a third party may be engaged to verify the physical assets or keep the assets in their possession till the loan is repaid. The lending platform **602** may issue loyalty points **614** to borrowing peers **600** and lending peers **604** upon successful repayment of loans, to incentivize the borrowing and lending peers **600**, **604** to use the lending platform again for borrowing and lending.

Referring now to FIG. 13 the multi-signature collateral contract used by the peer-to-peer lending system shown in FIG. 12 is described in more detail. Collateral tokens are stored in a multi-signature wallet contract **700**. Borrower **702**, Lender **706**, Lending Platform **704** and optional third-parties **708** hold keys to the multisig wallet contract **700**. The contract requires M-of-N signatures, typically a majority, (e.g. 2-of-3 or 3-of-5) to release collateral.

Referring now to FIG. 14 a process flow for the chaining of loans is described in more detail. The lending platform supports chaining loans where a borrowing/lending peer who has a good credit rating can borrow at low interest rates and lend to one or more peers who have low credit rating at higher interest rates. For example, Peer C **752** has good credit rating and sends a loan request **760** and borrows **762** from Peer D **754** at low interest rates. Peer C **752** receives loan requests **758**, **766** from Peers A and B **750**, **756** who have low credit rating or risk profile, and then send loans **764**, **768** to Peers A and B **750**, **756**, respectively, at higher interest rates. A loan can be partitioned into subloans with different terms. Lenders can fund a portion or fraction of a loan request. Thus a loan could be satisfied with a dozen

14

microloans each at different rates. For example, once a big lender jumps in for 30% of loan, small lenders can jump in to lend at a lower interest rate. A borrower with low risk can float a loan but open only 25% for bid to a high value lenders (such as institutions or banks). The borrower may then open up the loan to the smaller lenders who know the high value lenders will have vetted this borrower. Lending peers can buy a bundle of loans at a particular risk for a price or resell loans. The lending platform allows creating a market for users to buy, pool and resell loans. The lending platform may allow a loan to be written off if certain conditions may be met. For example, if a philanthropist funds a clinic and they treat five hundred patients in a month, then their loans can get a reduced rate, or if a farmer creates two jobs his loan may be forgiven.

Referring now to FIG. 15 a process for lending with cryptocurrency or tokens as collateral where the borrower successfully repays the loan is described in more detail. A Borrower **800** creates a loan request with amount requested and loan terms at step **808**. The lending platform **802** creates a loan contract **810** and advertises the loan request to lenders at step **812**. A Lender **804** agrees to fund the loan at step **814**. Next, the Borrower **800** deposits cryptocurrency or tokens as collateral in a collateral contract **818** at step **816**. The Lender **804** funds the loan at step **820**. The loan amount is released to the Borrower **800** at step **822**. The Borrower **800** pays loan installments to the Lending Platform **802** at steps **824** and **828** which are released to the Lender **804** at steps **826** and **830**. When the loan repayment is complete, the Collateral is released to the Borrower **800** at step **832**, such release being recorded to the collateral contract **818**.

Referring now to FIG. 16 a process for lending with cryptocurrency or tokens as collateral where the borrower fails to repay the loan, is described in more detail. A Borrower **850** creates a loan request on a lending platform **852** with an amount requested and loan terms at step **858**. The lending platform **852** creates a loan contract **860** and advertises the loan request to lenders at step **862**. A Lender **854** of N lenders **856** to whom the loan request is advertised agrees to fund the loan at step **864**. Next, the Borrower **850** deposits cryptocurrency or tokens as collateral in a collateral contract **868** at step **866**. The Lender **854** funds the loan at step **870**. The loan amount is released to the borrower at step **872**. When the Borrower **850** fails to repay the loan as indicated at step **876**, the Collateral is released to the Lender at step **874**.

Referring now to FIG. 17 a process flow for lending with physical assets as collateral, is described in more detail. A Borrower **902** creates a loan request on a lending platform **904** with an amount requested and loan terms at step **858**. The lending platform **904** creates a loan contract **910** and advertises the loan request to lenders at step **912**. A Lender **906** agrees to fund the loan at step **914**. Next, the Borrower **902** transfers physical assets (such as gold, diamonds or title to real-estate property) to a Third Party **900** at step **916**. The Third Party **900** tokenizes the assets and transfers the tokens to the borrower at step **918**. The Borrower **902** deposits these tokens as collateral to the lending platform **904** in a Collateral Contract **922** at step **920**. The Lender **906** funds the loan at step **924**. The loan amount is released to Borrower at step **926**. The Borrower repays the loan installment to the lending platform **904** at step **931** and the funds are released to the lender **906** at step **930**. When the loan repayment is complete the lending platform **904** releases the Collateral (tokens) is released to the Borrower **902** at step **932**. Next, the Borrower

15

902 transfers tokens to the third-party 900 at step 934. The third-party 900 then returns the physical assets to the Borrower 902 at step 936.

Referring now to FIG. 18 transaction fees involved for buying and selling of nCash coins is described in more detail. nCash coins can be purchased by paying in a fiat currency (such as USD) using credit/debit card 950 or ACH bank transfer 952, or by paying in a cryptocurrency 954 (such as Bitcoin, Ether). There are different transaction fees for buying coins with credit/debit card 960, ACH bank transfer, whether automated through an app 962 or manually 964, or cryptocurrency 970. For transactions between the nCash network 956 (such as sending coins to another user or merchant) does not involve any transaction fee. For selling coins and withdrawing coins to a linked bank account 958, a transaction fee. for automated transactions through an app 866 or manual transactions 968. is involved.

Referring now to FIG. 19 an illustration of smart contracts related to the lending platform and the interactions of borrowers and lenders with the smart contracts is described in more detail. An Identity Smart Contract 1012 is used to link blockchain accounts to real users, such as an account of a borrower 1000 or a lender 1002. The identity information provided by the borrower 1000 at step 1004 is recorded in the identity smart contract 1012 in original or hashed form. Similarly the identity information provided by the lender 1002 at step 1020 is recorded in the identity smart contract 1012 in original or hashed form. A Credit Rating & Reputation Smart Contract 1014 is used to track credit scores and reputation of a borrower 1000. The credit score of the borrower 1000 is recorded at step 1006 and updated on each new loan request, loan repayment or loan default. A Collateral Smart Contract 1016 is used to manage locking up and release of collateral, such as cryptocurrency tokens or physical assets which may be represented in a tokenized form. The borrower 1000 deposits the collateral tokens to the collateral smart contract 1016 at step 1008. A Loan Smart Contract 1018 is used to enforce loan terms and manage release, repayment or extension of loans. The information related to the borrower's 1000 loan requests, loan disbursement received or loan repayment completion is recorded in the loan smart contract 1018. Similarly, the information related to the lender's 1002 loan offers, loan disbursement completion, or loan repayment received is recorded in the loan smart contract 1018. The smart contracts 1012, 1014, 1016 and 1018 are deployed on the blockchain network 1026.

Referring now to FIG. 20 an illustration of a process for issuing cashback and discounts using smart contracts, is described in more detail. A customer 1050 makes a transaction to a merchant with coupon code meeting cashback or discount conditions at step 1052. An incentives smart contract 1054 checks cashback or discount rules comprised thereby and triggers a cashback or discount if the transaction meets the cashback or discount criteria at step 1056. When a cashback or discount is triggered, the token contract 1058 is updated and tokens are transferred from the merchant's account to the customer's account. The customer 1050 receives a cashback or discount notification at step 1060. The smart contracts 1054 and 1058 are deployed on the blockchain network 1064 at step 1062.

Referring now to FIG. 21 an illustration of the peer-to-pool-to-peer (P2P2P) lending model, is described in more detail. The lenders 1100, 1102, 1104 contribute to a lenders pool 1108 with conditions. A lender's condition to lend money may include the amount to lend, the duration of the loans, and expected returns. The loans are distributed from

16

the lenders pool 1108 with conditions. Borrowers 1118, 1120, 1122 may submit borrower's requests 1114 from the lenders pool 1108 through a lending platform 1110. Each borrower request may comprise the borrower's conditions for a loan. A borrower's condition for borrowing money may include the amount to borrow, the duration of the loan, and an acceptable interest rate.

A matching engine 1112 in the lending platform 1110 uses smart contracts 1116 to ensure the high level (pool level) and low level (borrower and lender) constraints are satisfied. A borrower's requests to borrow money are matched automatically to the lenders 1100, 1102, 1104 and lending pool's 1108 conditions using smart contracts 1116. Each lender pool (such as pool 1108) is represented by a smart contract (such as smart contract 1124) in the lending platform 1110 which controls the pool level behavior and handles conditions such as different time periods and expected returns for the lenders 1100, 1102, 1104 and substitution of lenders who exit the pool 1108 with new lenders, as some of the lenders to the pool 1108 may have different time periods and they will exit and be substituted by new lenders. Loans are distributed from lender pools 1108 with conditions.

The peer-to-pool-to-peer (P2P2P) lending model is more efficient than the existing peer-to-peer (P2P) lending models, especially when there are large number of lenders/investors who want to lend loans. Each lender/investor contributes a different amount of money and specifies the minimum interest they would like to receive and the period of their loan amounts. Similarly, the borrowers specify similar terms such as the amount of money to borrow, duration and acceptable rate of interest. In the P2P2P lending model the lender's money is pooled into one lending pool and then lent out to multiple borrowers, while smart contracts assure payouts to lenders and payments to borrowers, while some lenders exist and some borrowers' payback. This allows the "pool" of money that is used for lending, while at the lower level smart contracts ensure all lower agreements are kept. Lenders' and borrowers' contributions and withdrawals continually occur, while the pool remains active as new borrowers and lenders join and others may leave. A lender may end up lending to N loans and a borrower may end up borrowing from M lenders over a period where only P lenders are active at any time (where $M > N$ and $M > P$). The smart contracts are thus critical to maintain the integrity of the records. In the P2P2P lending model, the transactions for pools merge lower level transactions between peers inside the blockchain.

Furthermore, it is contemplated and included within the scope of the invention that a variety of loans may be executed utilizing this systems and other systems disclosed herein. The types of loans requested by borrowers, and offered by lenders, may include larger value loans, such as those typically offered by banks, but may also include smaller value loans, including those for individual consumer transactions (e.g. a routine, daily transaction for the purchase of consumer goods, groceries, etc.) performed at a merchant terminal. Additionally, loan requests may also take the form of other transfers of value aside from fiat currency, such as requests for cryptocurrency, credit towards a future transaction, an exchange of tokens having value, and the like.

Referring now to FIG. 22 an illustration of a lending pool generator for generating lending pool smart contracts is described in more detail. Each lender 1200, 1202, 1204 contributes 1206 to a lending pool with conditions including the amount of money to lend, duration of lending and expected returns. Lenders 1200, 1202, 1204 can have different conditions and may contribute to one or more lending

17

pools. A lending pool smart contract generator **1208** is used to generate smart contracts **1210**, **1212**, **1214** which represent the lending pools.

Referring now to FIG. **23** an illustration of a matching engine for matching borrowers to lending pools is described in more detail. Each borrower **1250**, **1252**, **1254**, **1256** requests money with conditions including the amount of money to borrow, duration for which money is to be borrowed and acceptable rate of interest. A matching engine **1258** matches the borrowers **1250**, **1252**, **1254**, **1256** to lending pool smart contracts **1260**, **1262**, **1264** such that the borrower level and pool level conditions are satisfied. A borrower **1250**, **1252**, **1254**, **1256** may be matched to more than one lending pool.

Referring now to FIG. **24** an illustration of feeding external data to lending pool contracts using an oracle is described in more detail. Lending pool and related smart contracts **1304** are deployed on a blockchain network **1306**. An oracle **1302** is used to feed in external or dynamic information (such as exchange rates, market value of collateral) to the lending pool smart contracts. The oracle **1302** may obtain such information from external sources and the web **1300**.

Referring now to FIG. **25** an illustration of channels and triggers for lending pools is described in more detail. Lending pools **1324**, **1326**, **1328** comprising Lenders **1320** and distributing to Borrowers **1330** can have channels **1332**, **1334** between them for transfer of pooled funds between the pools based on external triggers **1322**. Moving funds from one pool to another pool may be required when a pool is not performing well and the high-level (pool-level) and low-level (lender and borrower level) constraints are not being satisfied. The P2P2P lending platform may monitor the performance of each lending pool and generate triggers for transfer of funds from one pool to another.

Referring now to FIG. **26** an illustration of the smart contracts involved in a lending pool is described in more detail. Each lender **1352** is represented by an individual smart contract **1358** in the lending pool **1350**. Similarly, each borrower **1354** is represented by an individual smart contract **1360** in the lending pool **1350**. The lender smart contracts **1358** link lenders **1352** to the lending pool **1350** via the lending pool contract **1356**. The borrower smart contracts **1360** link borrowers **1354** to the pool lending **1350** via the lending pool contract **1356**. There is no direct link between the lenders **1352** and borrowers **1354** like traditional smart contracts used in blockchain based peer-to-peer lending solutions.

In current lending schemes (especially computer-implemented lending schemes or blockchain based peer-to-peer lending schemes), if there are a large number of investors in a lending pool, each specifying an investment amount they would like to invest, the rates they would like to receive in combination with time periods (such as 2.3% over 3 months, or 2.2% over 6 months) and with various exit strategies, and large number of borrowers specifying various terms and repayment periods and early payoff options, the following problems arise:

Manual reconciliation is not possible when the number of active and passive investors enter and leave the pool.

A scalable and secure solution is not possible.

Abstracting the lenders and borrowers with “linked” smart contracts in a lending pool solves the problems of manual reconciliation and scalability. Additionally, this approach provides the following benefits:

18

Borrowers with good credit may borrow at better rates and lend to other borrowers with bad credit with the borrowed money at higher rates.

A seamless lending environment can be created with options to borrow or lend at certain rates and offer these derivatives for trading as well.

Referring now to FIG. **27** an illustration of pool-of-pools comprised of multiple lending pools, is described in more detail. Multiple lending pools can be clubbed together to create a pool-of-pools. The pool-of-pools approach is beneficial for highly volatile pools in which borrowers and lenders keep entering and exiting and it is difficult to meet the high-level (pool-level) and low-level (lender and borrower level) constraints. Combining multiple pools into a pool-of-pools brings stability to the P2P2P lending platform. A pool-of-pools approach may comprise a plurality of lending pools **1402**, **1404**, **1406**, **1408** that each interact with a pool of pools **1400**. Each of the plurality of lending pools **1402**, **1404**, **1406**, **1408** may comprise borrower smart contracts with respective borrowers **1412**, **1420**, **1424**, **1428** and lender smart contracts with respective lenders **1410**, **1418**, **1422**, **1426**. Additionally, some borrowers **1416** and lenders **1414** may interact directly with the pool of pools **1400**.

Referring now to FIG. **28** an illustration of lending pool smart contract structures and transactions is described in more detail. A contract owner (or the lending platform) **1522** creates and owns **1520** a lending pool contract **1500**. The lending pool contract **1500** is created from an externally owned account (EOA) **1518** of the contract owner (or the lending platform) **1522** when a create contract transaction **1510** is performed by the EOA **1518** thereby creating **1502** the lending pool contract **1500**. Lenders **1524** use their EOAs **1528** to send transactions **1532** to the lending pool contract **1500**. A lender **1524** can join **1506** a lending pool by sending a joinPool transaction **1514**. Borrowers **1526** use their EOAs **1530** to send transactions **1534** to the lending pool contract **1500**. A borrower **1526** can repay a loan **1508** taken from the lending pool by sending a repayLoan transaction **1516**.

Referring now to FIG. **29** an exemplary classification of lending pools based on their risks and returns is described in more detail. Lending pools are classified based on their risks and returns. The lending pools with lower risk have lower returns and the lending pools with higher risk have higher returns. The risk level for a lending pool is computed based on the reputation and credit scores of the borrowers and lenders linked to the pool. The pools which lend money to borrowers with high credit scores usually lend at low rates of interest as these loans are considered to be safe. Similarly the pools which lend money to borrowers with low credit scores usually lend at high rates of interest as these loans are considered to be risky. In some embodiments, the loan risk may be categorized as low, medium, and high, and the returns may also be characterized as low, medium and high. This may result in risk-reward categories of low risk-high returns **1600**, medium risk-high returns **1602**, high risk-high returns **1604**, low risk-medium returns **1608**, medium risk-medium returns **1618**, high risk-medium returns **1620**, low risk-low returns **1612**, medium risk-low returns **1614**, and high risk-low returns **1616**. Most lending pools will fall into one of low risk-low returns **1612**, low risk-medium returns **1608**, medium risk-medium returns **1618**, medium risk-high returns **1602**, and high risk-high returns **1604**.

Referring now to FIG. **30** an illustration of an alliance of merchants with interoperable loyalty points is described in more detail. Customers **1150** and **1152** make payments **1154**

at affiliated merchant stores **1156** using nCash. The merchant payments are processed **1158** by the nCash network **1160**. Customer's receive loyalty points that work at any merchant in the alliance or network or affiliated merchants **1156**. These loyalty points are interoperable across all the merchants in the alliance and can be applied towards a discount for the next purchase.

Referring now to FIG. **31** an illustration of a distributed messaging framework, is described in more detail. The distributed publish-subscribe messaging framework described here is referred to as Bulletin Board Messaging Framework (BBMF) or "Bulletin Board". The Bulletin Board Server **1678** manages Topics **1680**, **1682**. Bulletin Board Clients can be Publisher/Producer Clients **1670**, **1672** or Consumer/Subscriber Clients **1688**, **1690**. The Publisher/Producer Clients **1670**, **1672** publish data or messages to Topics **1680**, **1682**. Data pushed to the topics **1680**, **1682** from the Publisher/Producer Clients **1670**, **1672** may originate from data sources **1650**, which may comprise smart contracts **1652**, oracles **1654**, logs **1656**, sensors **1658**, records **1660**, databases **1662**, streams **1664**, and events **1668**. Consumer/Subscriber Clients **1688**, **1690** consume data from the Topics **1680**, **1682**, receiving messages **1684**, **1686** from the Bulletin Board Server **1678**. Bulletin Board Server **1678** supports a plug-in Message Storage Backend **1692** to store and replay messages. The Message Storage Backend **1692** persists the messages using two options: (1) a Cloud Database or Cloud Storage **1694**, (2) Decentralized Storage Platform (such as IPFS or Swarm) **1698** with regular checkpointing of message hashes to a Blockchain **1696**. Messages in the Bulletin Board can be either Ephemeral or Persistent. Ephemeral messages are not stored by the Message Storage Backend. For Persistent messages Time-to-Live (TTL) can be specified. The Producers and Consumers support both Cloud and Blockchain protocols such as HTTP-REST or Web3 for Ethereum. This allows existing Smart Contracts (such as Solidity smart contracts) to publish and consume data to/from the Bulletin board, and existing Oracles to feed-in data from the web to the smart contracts through the Bulletin board. A smart contract implemented in the Solidity language, for example, is a data source which generates notifications in the form of Solidity events which are published to the Bulletin Board server by a Publisher Client. Solidity smart contracts require an external Publisher Client to publish messages to the Bulletin board. Extensions to smart contract languages such as Solidity may be implemented to support Bulletin board APIs to publish data without the need for an external publisher client. These extensions and/or stubs can be through use of pragma directives that may be pre-processed by pre-processors to generate suitable code for implementing the interfaces to the bulletin board, or they could involve extensions to the language itself to support global variable names. Topics are managed in-memory with regular snapshots on the disk which are later stored in the Message Storage Backend **1692**. A compaction process is defined for moving the messages in the snapshots to the Message Storage Backend **1692** (Cloud and/or Blockchain). The Bulletin Board itself may be implemented in part through use of a cloud-based service and/or a blockchain and may also include hardware accelerators (such as ASICs or FPGAs) and graphical processing units (GPUs) to provide this high throughput low latency service. Additional redundancy, authorization, and encryption layers may also be provided in hardware and software using known techniques for cloud and internet networks to secure the messages and values stored from system failures or hacking attacks.

The BBMF is designed for high throughput and low latency messaging. The Bulletin Board server **1678** can be deployed in a cloud computing environment and scaled either vertically or horizontally based on demand. In vertical scaling larger virtual machine instance size (in terms of compute capacity, memory and storage) is used for the Bulletin Board server. In horizontal scaling multiple instances of the Bulletin Board server are launched with each instance managing a subset of the topics managed by the Bulletin Board.

BBMF supports both push/pull and publish/subscribe data ingestion models and data delivery models. Furthermore, the data delivery may be either at-least once delivery or exactly-once delivery. BBMF can be implemented in hardware and software, using a combination of servers, ASICs/FPGAs and GPUs as part of a cloud-based or a locally configured computing system.

As Bulletin Board is a distributed messaging framework, a trade-off exists between consistency and availability. This trade-off is explained with the CAP Theorem, which states that under partitioning, a distributed data system can either be consistent or available but not both at the same time. Bulletin Board adopts an eventually consistent model. In an eventually consistent system, after an update operation is performed by a writer, it is eventually seen by all the readers. When a read operation is performed by a consumer, the response might not reflect the results of a recently completed write operation.

The Bulletin Board messaging framework supports prioritized processing of messages. The priority can be set in the message header field. Various priority classes for messages can be defined and specified in the priority header field. This priority classification of messages is crucial for the Peer-to-Pool-Peer (P2P2P) lending system when a large number of updates have to be propagated to linked smart contracts in the lending system.

Referring now to FIG. **32** an illustration of the consumer/subscriber actions supported in the publish-subscribe messaging framework are described in more detail. For Consumers or Subscribers **1708** various actions Rules & Triggers **1710** and Actions **1712** can be defined. Rules & Triggers **1712** specify how to filter and select data and trigger actions. The supported actions **1716** include Smart Contract Transaction **1718**, Webhook Trigger **1720**, Log to External Data Store **1722**, Email Notification **1724**, SMS Notification **1726**, and Mobile Push Notification **1728**. An action is performed when a message **1706** matching a rule is received (for example temperature >60 or ETH price <\$500) from the Bulletin Board Server **1700**, being related to one of the Topics **1702**, **1704** managed by the Bulletin Board Server **1700**. The message may be transmitted to the Consumer or Subscriber Client **1708** by any means or method known in the art, including, but not limited to, HTTP/REST applications and WebSocket. The smart contract transaction action is particularly useful for the P2P2P lending system described above where a large number of linked smart contracts (such as smart contracts in a lending pool) can be executed when a message notifying a change in the lending conditions is received.

Referring now to FIG. **33** an illustration of a smart contract data source that uses an external publisher client to publish messages to the publish-subscribe messaging framework is described in more detail. A smart contract data source **1800** such as a Solidity smart contract generates notifications or events **1802**. A publisher/producer client **1804** watches for the notifications or events generated by the smart contract **1800**. When a notification or event is gener-

ated, the messages are published **1806** to the topics **1810**, **1812** managed by the Bulletin Board **1808**. These messages are delivered **1814** to the consumer/subscriber client **1816** which has subscribed to the topics **1810**, **1812**. The consumer/subscriber client **1816** has a smart contract transaction action configured which sends transactions **1818**, **1820** to the linked smart contracts **1822**, **1824** on receiving the messages.

Referring now to FIG. **34** an illustration of a smart contract data source that uses an integrated publisher client to publish messages to the publish-subscribe messaging framework, is described in more detail. A smart contract data source with integrated publisher/producer client **1850** generates notifications or events. The notifications or events are published as messages **1852** to the topics **1856**, **1858** managed by the Bulletin Board **1854**. These messages are delivered **1860** to the consumer/subscriber client **1862** which has subscribed to the topics **1856**, **1858**. The consumer/subscriber client **1862** has a smart contract transaction action configured which sends transactions **1864**, **1866** to the linked smart contracts **1868**, **1870** on receiving the messages.

Referring now to FIG. **35** an illustration of the message format for the publish-subscribe messaging framework is described in more detail. The Message Type field **1750** defines the type of the message. Supported message types in the Bulletin Board framework are as follows:

CONNECT: A CONNECT message is sent by a client (producer or consumer) to connect to the server.
 DISCONNECT: A DISCONNECT message is sent by a client to disconnect from the server.
 PUBLISH: Used to publish a new message
 SUBSCRIBE: Used to subscribe to a topic managed by the Bulletin Board
 UNSUBSCRIBE: Used to unsubscribe from a topic
 PINGREQUEST: Used to send a ping request to the server
 PINGRESPONSE: Used to respond to a ping request
 DATAREQUEST: Used to request a message or data item
 DATARESPONSE: Used to respond to a request for a message or data item.

The Data Payload field **1752** includes the message as a JSON data payload. The message may be signed by the sender and/or encrypted. The Topics field **1754** includes a list of topics to which the message is published. The Headers field **1756** includes headers such as:

Sender or receiver identity
 Message signature
 QoS Level
 Priority
 Persistent or Ephemeral message
 Additional flags to help in processing of message

The Time-to-Live (TTL) field **1758** is used to specify the validity or life of the message. The Nonce field **1760** is an integer value which can be used to prove that a given amount of work was done in composing the message.

Referring now to FIG. **36** an illustration of a blockchain checkpointing approach in the publish-subscribe messaging framework, is described in more detail. When using Blockchain and Decentralized Storage Platform (IPFS or Swarm) based Message Storage Backend, the messages **1780** are hashed **1782** and are added to a Merkle Tree **1784**. The root hash **1786** of the Merkle Tree **1784** (after every N messages) is recorded on the Blockchain **1788**. This ensures messages cannot be tampered with later.

Referring now to FIG. **37** an illustration of a global variable name system being updated by a consumer of the

publish-subscribe messaging framework, is described in more detail. The Global Variable Name System (GVNS) **1916** maintains records of global variables and the owners and resolvers for the global variables. Data sources **1900** such as a smart contract, oracle, log, sensor, record, database, stream or event, produce data or notifications which are sent to a publisher/producer client **1902**. The publisher/producer client **1902** publishes the data or notification as a message **1904** to one or more topics **1908**, **1910** managed by the Bulletin Board server **1906**. The consumer/subscriber client **1914** receives the messages **1912** and updates the value of global variables registered in the GVNS **1916**. Smart contracts **1918**, **1920**, **1922** reference the global variable registered in the GVNS **1916**.

Referring now to FIG. **38** an illustration of the architecture of a global variable name system, is described in more detail. The Global Variable Name System (GVNS) **1950** comprises Registrar **1952**, Registry **1954** and Resolver **1956** components. The Registrar **1952** is responsible for registering new variable names, updating the resolver for a variable name, and transferring the ownership of a variable. The Registry **1954** is responsible for recording the owner and resolver of a variable name, and returning the resolver for a variable name. The Resolver **1956** is responsible for resolving a variable name to a value and updating the value of a registered variable. The steps involved in registering a global variable in the GVNS **1950**, updating the variable and retrieving the current value of the variable are explained as follows. At step-1 **1958** a user **1980** sends a request (through an externally owned account **1978** or a smart contract **1976**) to register a new global variable name (for example, ncash-supply) to the Registrar **1952**. At step-2 **1960**, the Registrar **1952** sets the owner and resolver for the variable in the Registry **1954**. At step-3 **1970**, a consumer/subscriber client **1972** or a smart contract **1974** sends a request to update the value of the global variable to the Resolver **1956**. At step-4 **1962**, a smart contract **1966** requests the value of the global variable from the Registry **1954**. At step-5 **1964**, the Registry **1954** retrieves the Resolver **1956** for the variable. At step-6 **1968**, the Resolver **1956** returns the value of the global variable.

Referring now to FIG. **39** an illustration of global variable sharing across smart contracts is described in more detail. The Lending Pool smart contract **2004**, Lending Request smart contract **2002** and Loan smart contract **2006** are linked smart contracts in a Peer-to-Pool-Peer (P2P2P) lending system that are used in loan making and loan servicing processes. The Lending Request smart contract **2002** is used in the loan making process. Borrowers send lending requests to the lending system and a Lending Request smart contract is created for each lending request. The Lending Pool smart contract **2004** is used to manage a lending pool. When the lending system matches a lending request to a lending pool, a new Loan smart contract **2006** is created. The Loan smart contract **2006** manages the loan servicing aspects of a loan from the time the loan is disbursed until the loan is paid off. The Loan smart contract **2006** captures the loan details such as loan principal, loan interest rate, address of lending pool contract from where the loan is disbursed as state variables. Loan smart contract **2006** also registers global variables **2042** such as for the loan amount repaid (loanAmountRepaid) and loan status (loanStatus). The Lending Pool smart contract **2004** and Lending Request smart contract **2002** have global variables **2022**, **2012** which are registered **2010**, **2008** with the Global Variable Name Systems (GVNS) **2000** (lendingPool AmountRaised, lendingPool numLenders,

23

lendingRequest AmountRequested). These global variables are referenced **2032** in the Loan smart contract **2006**.

Each of the smart contracts **2002**, **2004** and **2006** have state variables **2014**, **2024**, **2034**, functions **2016**, **2026**, **2036**, modifiers **2018**, **2028**, **2038**, and events **2020**, **2030**, **2040**, which are existing elements/types/constructs in the Solidity smart contracts language. Support for global variables which are shared across multiple smart contracts through GVNS **2000** within Solidity smart contracts language, is added through extensions to the Solidity language specification. Furthermore, extensions are done within the Ethereum Virtual Machine (EVM) which is the runtime environment for smart contracts in Ethereum to add support for global variables shared through GVNS **2000**. While Solidity and Ethereum have support for a limited set of global variables that provide information about the blockchain (such as block.coinbase, block.difficulty, block.gaslimit, block.number, block.blockhash, block.timestamp, msg.data, msg.gas, msg.sender, msg.value, tx.gasprice, tx.origin, this.balance, addr.balance), it is not possible for two or more linked smart contracts to share global variables. This additional support for global variables is enabled by the GVNS **2000**, extensions to the Solidity language specification and extensions to the Ethereum Virtual Machine (EVM). The global variable support is crucial for linked smart contracts (such as in a P2P2P lending system) to work.

The BBMF when used in combination with GVNS could provide information to an “analytics engine” as to the number of updates of the global variables and their type, and also to “advertising engines” as to the global variables referenced and their types.

Referring now to FIG. **40** an exemplary implementation of a Bulletin Board Publisher/Producer client and Consumer/Subscriber client is described in more detail. In the Publisher/Producer client implementation an instance of the Bulletin Board client class is created. The connect() method of the client class is used to establish a connect to the Bulletin Board server by passing the Bulletin Board server address, clientID and client secret. The publish() method of the client class is used to publish a message to the Bulletin Board server. The message object published to the Bulletin Board server contains the list of topics, data payload, headers, time-to-live and nonce fields. In the Consumer/Subscriber Client implementation, subscribe() method of the client class is used to subscribe to all or selected topics on the Bulletin Board server. A callback function on_message() is defined which is executed every time a new message is delivered.

Referring now to FIG. **41** an exemplary interface of the nCash mobile application is described in more detail. The exemplary interface shows options to buy coins, send coins, receive coins, pay coins at a merchant, sell or withdraw coins, chat and transact with contacts, view list of transactions, loans and settings options. The customer's account details such as account number, name and account balance is also shown.

Referring now to FIG. **42** an exemplary interface of the nCash mobile application showing peer-to-peer lending options is described in more detail. A customer is eligible to request loans after completing the lending profile that includes customer's financial and education information. Customer can view the nCash credit score from the mobile application. Borrowing peers (borrowers), can create new loan requests, view the status of existing loan requests, view loan offers received from lending peers (lenders) for the loan requests, and repay a loan. Lending peers (lenders) can view open loan requests submitted by all borrowing peers (bor-

24

rowers) on the network, search for specific loan requests by date range or loan request ID, send loan offers for the loan requests, and release funds for accepted loan offers.

Referring now to FIG. **43** an exemplary interface of the nCash mobile application showing different types of transactions is described in more detail. The transactions involved are of following types:

Transaction for buying new coins by paying in fiat currency (such as USD) with credit/debit card or ACH bank transfer

Transaction for buying new coins by paying in cryptocurrency (such as Bitcoin)

Transaction for selling coins and withdraw coins to a linked bank account

Transaction for transferring coins to another user

Transaction for a cashback received on availing a cashback offer.

Transaction for coins received on claiming a voucher

Referring now to FIG. **44** an exemplary interface of the nCash mobile application showing chats and payments interface is described in more detail. The chats and transactions interface allows two customers to chat with each other and send or request payments. A payment request received by a user can be approved or declined from the chats and transactions interface itself.

Referring now to FIG. **45** an illustration of the nCash mobile application features for different types of accounts is depicted.

All of the above-described methods are performable on computerized systems, such systems comprising a processor, a data store (such as memory) positioned in communication with the processor, and a network communication device position in communication with the processor and operable to communicate across a network, as are all known in the art.

Some of the illustrative aspects of the present invention may be advantageous in solving the problems herein described and other problems not discussed which are discoverable by a skilled artisan.

While the above description contains much specificity, these should not be construed as limitations on the scope of any embodiment, but as exemplifications of the presented embodiments thereof. Many other ramifications and variations are possible within the teachings of the various embodiments. While the invention has been described with reference to exemplary embodiments, it will be understood by those skilled in the art that various changes may be made and equivalents may be substituted for elements thereof without departing from the scope of the invention. In addition, many modifications may be made to adapt a particular situation or material to the teachings of the invention without departing from the essential scope thereof. Therefore, it is intended that the invention not be limited to the particular embodiment disclosed as the best or only mode contemplated for carrying out this invention, but that the invention will include all embodiments falling within the scope of the appended claims. Also, in the drawings and the description, there have been disclosed exemplary embodiments of the invention and, although specific terms may have been employed, they are unless otherwise stated used in a generic and descriptive sense only and not for purposes of limitation, the scope of the invention therefore not being so limited. Moreover, the use of the terms first, second, etc. do not denote any order or importance, but rather the terms first, second, etc. are used to distinguish one element from another. Furthermore, the use of the terms a, an, etc. do not

25

denote a limitation of quantity, but rather denote the presence of at least one of the referenced item.

Thus the scope of the invention should be determined by the appended claims and their legal equivalents, and not by the examples given.

That which is claimed is:

1. A method of exchanging value across a blockchain network comprising:

receiving a first transaction smart contract comprising a transaction amount global variable name request and a transaction amount;

recording the first transaction to a second transaction smart contract on a first blockchain network;

registering the first transaction amount global variable name to a global variable name system, defining a transaction amount global variable;

defining a value of the transaction amount global variable responsive to the transaction amount;

receiving a second transaction smart contract comprising a second transaction global variable name request and a second transaction amount;

registering the second transaction global variable name request to the global variable name system, defining a second transaction global variable;

defining a value of the second transaction global variable responsive to the second transaction amount;

receiving a transaction notification comprising the second transaction global variable name and a transaction value;

recording the transaction notification to the second smart contract; and

updating the value of the second transaction global variable responsive to the transaction value.

2. The method of exchanging value of claim 1 wherein updating the value of the second transaction global variable comprises:

publishing the updated value of the second transaction global variable to a first managed topic on a first messaging server; and

transmitting the content published to the managed topic to a first subscriber;

wherein the receipt of the content published to the first managed topic by the first subscriber initiates a smart contract transaction for a first smart contract, the first smart contract being recorded on a first blockchain network.

3. The method of exchanging value of claim 1 wherein registering the transaction amount global variable, registering the second transaction global variable, and registering the registering the second transaction global variable each comprise performing a global variable registration process comprising:

receiving a request for to register a global variable name at a global variable name registrar from a user, defining a new global variable;

defining an owner for the new global variable at a global variable name registry;

defining a resolver for the new global variable at the global variable name registry; and

defining a value of the new global variable.

4. The method of claim 3 further comprising performing an updating procedure to update the value of the new global variable, the updating procedure comprising:

receiving a trigger generated by a smart contract data source on a first messaging server, the trigger comprising an updated value of the new global variable;

26

publishing the updated value comprised by the trigger to a first managed topic associated with the new global variable on the first messaging server; and

transmitting the updated value comprised by the trigger that is published to the managed topic to a first subscriber;

wherein receipt of the content published to the first managed topic by the first subscriber initiates a smart contract transaction for a first smart contract, the first smart contract being recorded on the first blockchain network.

5. The method of exchanging value of claim 1 further comprising:

receiving a collateral input; and

recording the collateral input to a collateral smart contract on the first blockchain network.

6. The method of claim 5 wherein the collateral input is a collateral token generated by:

receiving a tangible asset collateral deposit;

generating a collateral token associated with the tangible asset collateral deposit; and

transmitting the collateral token.

7. The method of claim 6 wherein the tangible asset is received by a third party and the collateral token is generated by the third party.

8. The method of exchanging value of claim 5 further comprising:

receiving a repayment notification;

recording the repayment notification to the second transaction smart contract;

updating the value of the second transaction global variable; and

recording a collateral release to the collateral smart contract.

9. The method of claim 5 further comprising:

receiving a default notification;

recording the default notification to the second transaction smart contract;

updating the value of the second transaction global variable; and

recording a collateral release to the collateral smart contract directed to the second transaction global variable.

10. The method of claim 5 wherein the collateral input comprises at least one of cryptocurrency or a collateral token.

11. The method of claim 1 further comprising:

receiving an installation payment;

recording an installation payment notification to the second transaction smart contract;

updating the second transaction global variable responsive to a value of the installation payment; and

transferring at least a portion of the value of the installation payment to an entity associated with the second transaction global variable.

12. The method of claim 1 wherein the first transaction smart contract further comprises a loan duration and a loan interest rate, collectively defining borrower conditions, the method further comprising:

registering a loan duration global variable name to the global variable name system, defining a loan duration global variable;

defining a value of the loan duration global variable responsive to the transaction amount;

registering a loan interest rate global variable name to the global variable name system, defining a loan interest rate global variable; and

27

defining a value of the loan interest rate global variable responsive to the loan interest rate.

13. The method of claim **12** further comprising:

receiving a plurality of lending offers from a plurality of lenders, each lending offer comprising an amount to lend, a loan duration, and expected returns, collectively defining lending pool conditions;

recording the plurality of lending offers, defining a lending pool, to a second transaction smart contract on the first blockchain network, the values of the lending offers of the plurality of lending offers defining lending pool conditions;

determining if the borrower conditions match the lending pool conditions;

matching a lending offer from the second transaction smart contract to the first transaction;

recording a borrower smart contract between the borrower and the second transaction smart contract; and

recording a lender smart contract between the lender associated with the matched lending offer and the second transaction smart contract.

14. The method of claim **12** further comprising:

receiving multiple pluralities of lending offers from a plurality of lenders, each lending offer comprising an amount to lend, a loan duration, and expected returns;

recording each plurality of lending offers, defining a lending pool, to a second transaction smart contract on the first blockchain network, the values of the lending offers of the plurality of lending offers defining lending pool conditions;

recording a plurality of second transaction smart contracts to a pool of pools smart contract on the first blockchain network;

determining if the borrower conditions match the lending pool conditions of any of the plurality of second transaction smart contracts comprised by the pool of pools smart contract;

matching a lending offer from the pool of pools smart contract to the first transaction;

recording a borrower smart contract between the borrower and the pool of pools smart contract;

recording a pool-to-pool smart contract between the pool of pools smart contract and the second transaction smart contract; and

recording a lender smart contract between the lender associated with the matched lending offer and the second transaction smart contract.

15. The method of claim **1** further comprising:

receiving borrower identity information associated with a borrower;

receiving a borrower credit rating; and

recording the borrower credit rating to a credit rating and reputation smart contract on the first blockchain network.

16. A method of exchanging value across a blockchain network comprising:

receiving a first transaction smart contract comprising a transaction amount global variable name request and a transaction amount;

recording the first transaction to a second transaction smart contract on a first blockchain network;

registering the first transaction amount global variable name to a global variable name system, defining a transaction amount global variable;

defining a value of the transaction amount global variable responsive to the transaction amount;

28

receiving a second transaction smart contract comprising a second transaction global variable name request and a second transaction amount;

registering the second transaction global variable name request to the global variable name system, defining a second transaction global variable;

defining a value of the second transaction global variable responsive to the second transaction amount;

receiving a transaction notification comprising the second transaction global variable name and a transaction value;

receiving a transaction notification;

recording the transaction notification to the second transaction smart contract;

updating a value of the second transaction global variable responsive to the transaction notification comprising the steps of:

publishing the updated value of the second transaction global variable to a first managed topic on a first messaging server; and

transmitting the content published to the managed topic to a first subscriber; and

transferring at least a portion of the value of the transaction notification to an entity associated with the second transaction global variable;

wherein the receipt of the content published to the first managed topic by the first subscriber initiates a smart contract transaction for a first smart contract, the first smart contract being recorded on a first blockchain network.

17. The method of claim **16** wherein the first transaction further comprises a loan duration and a loan interest rate, the method further comprising:

registering a loan duration global variable name to the global variable name system, defining a loan duration global variable;

defining a value of the loan duration global variable responsive to the transaction amount;

registering a loan interest rate global variable name to the global variable name system, defining a loan interest rate global variable; and

defining a value of the loan interest rate global variable responsive to the loan interest rate.

18. The method of claim **17** wherein the first transaction further comprises a loan duration and a loan interest rate, collectively defining borrower conditions, the method further comprising:

receiving a plurality of lending offers from a plurality of lenders, each lending offer comprising an amount to lend, a loan duration, and expected returns, collectively defining lending pool conditions;

recording the plurality of lending offers, defining a lending pool, to a second transaction smart contract on the first blockchain network, the values of the lending offers of the plurality of lending offers defining lending pool conditions;

determining if the borrower conditions match the lending pool conditions;

matching a lending offer from the second transaction smart contract to the first transaction;

recording a borrower smart contract between the borrower and the second transaction smart contract; and

recording a lender smart contract between the lender associated with the matched lending offer and the second transaction smart contract.

29

19. The method of claim 17 wherein the first transaction further comprises a loan duration and a loan interest rate, collectively borrower conditions, the method further comprising:

receiving multiple pluralities of lending offers from a plurality of lenders, each lending offer comprising an amount to lend, a loan duration, and expected returns; recording each plurality of lending offers, defining a lending pool, to a second transaction smart contract on the first blockchain network, the values of the lending offers of the plurality of lending offers defining lending pool conditions; recording a plurality of second transaction smart contracts to a pool of pools smart contract on the first blockchain network; determining if the borrower conditions match the lending pool conditions of any of the plurality of second transaction smart contracts comprised by the pool of pools smart contract; matching a lending offer from the pool of pools smart contract to the first transaction; recording a borrower smart contract between the borrower and the pool of pools smart contract; recording a pool-to-pool smart contract between the pool of pools smart contract and the second transaction smart contract; and recording a lender smart contract between the lender associated with the matched lending offer and the second transaction smart contract.

20. A system for exchanging value across a blockchain network comprising:
a processor;
a data store positioned in communication with the processor; and

30

a network communication device positioned in communication with each of the processor, the data store, and a network;

wherein the network communication device is operable to receive a first transaction smart contract comprising a transaction amount global variable name request and a transaction amount;

wherein the processor is operable to record the first transaction to a second transaction smart contract on a first blockchain network;

wherein the processor is operable to register the first transaction amount global variable name to a global variable name system, defining a transaction amount global variable;

wherein the network communication device is operable to receive a second transaction smart contract comprising a second transaction global variable name request and a second transaction amount;

wherein the processor is operable to register the second transaction global variable name request to the global variable name system, defining a second transaction global variable;

wherein the network communication device is operable to receive a transaction notification comprising the second transaction global variable name and a transaction value;

wherein the processor is operable to record the transaction notification to the second transaction smart contract; and

wherein the processor is operable to update a value of the second transaction global variable responsive to the transaction value.
